

CIC – 209: DATA STRUCTURES

Unit – I Arrays

Arrays

- An array is defined as a set of finite number of homogeneous elements or same data items.
- It means an array can contain one type of data only, either all integer, all float-point number or all character.
- The individual elements are typically stored in consecutive memory locations.
- The length of the array is determined when the array is created, and cannot be changed.
- Any component of the array can be inspected or updated by using its index.
 - *This is an efficient operation*
 - $O(1)$ = constant time

Arrays

- Some common operation performed on array are:
 - Creation of an array
 - Traversing an array
 - Insertion of new element
 - Deletion of required element
 - Modification of an element
 - Sorting of elements of an array
 - Merging of arrays
 - Searching for an element in the array

Different Types of Arrays

- **One-dimensional array:** only one index is used
- **Multi-dimensional array:** array involving more than one index
- **Static array:** the compiler determines how memory will be allocated for the array
- **Dynamic array:** memory allocation takes place during execution

1-D Array Representation in C/C++

Memory

- 1-dimensional array $x = [a, b, c, d]$
- map into contiguous memory locations
- $\text{location}(x[i]) = \text{start} + i$ (i.e. $x+i$)

Space Overhead

Memory

Space Overhead = 4 bytes for **start** (i.e pointer pointing to the array)

(excludes space needed for the elements of **x**)

2-D Arrays

The elements of a 2-dimensional array **a** declared as:

```
int a[3][4];
```

may be shown as a table

a[0][0]	a[0][1]	a[0][2]	a[0][3]
a[1][0]	a[1][1]	a[1][2]	a[1][3]
a[2][0]	a[2][1]	a[2][2]	a[2][3]

Rows Of A 2D Array

a[0][0]	a[0][1]	a[0][2]	a[0][3]	→ row 0
a[1][0]	a[1][1]	a[1][2]	a[1][3]	→ row 1
a[2][0]	a[2][1]	a[2][2]	a[2][3]	→ row 2

Columns Of A 2D Array

2-D Array Representation in C/C++

2-dimensional array **x**

a, b, c, d

e, f, g, h

i, j, k, l

view 2-D array as a 1-D array of rows

x = [row0, row1, row 2]

row 0 = [a,b, c, d]

row 1 = [e, f, g, h]

row 2 = [i, j, k, l]

and store as **4** 1-D arrays

2-D Array Representation in C/C++

Space Overhead

Space Overhead = Overhead for 4 1-D arrays
= 4 * 4 bytes
= 16 bytes
= (Number of Rows + 1) x 4 bytes

Array Representation in C/C++

- This representation is called the **Array-of-Arrays** representation.
- Requires contiguous memory of size 3, 4, 4, and 4 for the 4 1-D arrays.
- 1 memory block of size **Number of Rows** and **Number of Rows** blocks of size **Number of Columns**

Row-Major Order (RMO) Mapping

- Consider 2-D array `x[3][4]`:

`a b c d`
`e f g h`
`i j k l`

- Convert into 1-D array `y` by collecting elements by rows.
- Within a row elements are collected from left to right.
- Rows are collected from top to bottom.
- We get 1-D array `y[] = {a, b, c, d, e, f, g, h, i, j, k, l}`

row 0	row 1	row 2	...	row i		
-------	-------	-------	-----	-------	--	--

Locating Element $x[i][j]$ in RMO

- assume array x has r rows and c columns
- each row has c elements
- i rows to the left of i^{th} row
- so ic elements to the left of $x[i][0]$
- so $x[i][j]$ is mapped to position

$ic + j$ of the 1-D array
or $(i \times \text{no_of_columns} + j)$

Column-Major Order (CMO) Mapping

- Consider 2-D array $x[3][4]$:

$a\ b\ c\ d$

$e\ f\ g\ h$

$i\ j\ k\ l$

- Convert into 1-D array y by collecting elements by columns.
- Within a column elements are collected from top to bottom.
- Columns are collected from left to right.
- We get 1-D array $y[] = \{a, e, i, b, f, j, c, g, k, d, h, l\}$

Locating Element $x[i][j]$ in CMO

0	r	2r	3r	j _r		
col 0	col 1	col 2	...	col j		

- assume array x has r rows and c columns
- each column has r elements
- j columns to the left of j^{th} column
- so j_r elements to the left of $x[0][j]$
- so $x[i][j]$ is mapped to position
 $i + j_r$ of the 1-D array
or $(i + j \times \text{no_of_rows})$

Space Overhead

row 0	row 1	row 2	...	row i		
-------	-------	-------	-----	-------	--	--

OR

col 0	col 1	col 2	...	col j		
-------	-------	-------	-----	-------	--	--

4 bytes for **start** of 1-D array +
4 bytes {either for c (number of columns) or
for r (number of rows)
= 8 bytes

Disadvantage

Need contiguous memory of size **rc**.

Matrix

Table of values. Has rows and columns, but numbering begins at 1 rather than 0.

a b c d row 1

e f g h row 2

i j k l row 3

- Use notation **x(i,j)** rather than **x[i][j]**.
- May use a 2-D array to represent a matrix.

Sparse Matrices

Matrix → table of values

Sparse matrix → #nonzero elements/#elements is small.

0 0 3 0 4	
0 0 5 7 0	Row 2
0 0 0 0 0	
0 2 6 0 0	
Column 4	

4 x 5 matrix

4 rows

5 columns

20 elements

6 nonzero elements

Representation Of Sparse Matrices

- Single linear list in Row-Major Order.
- Scan the nonzero elements of the sparse matrix in row-major order (i.e., scan the rows left to right beginning with row 1 and picking up the nonzero elements)
- Each nonzero element is represented by a triple or 3-tuple
(row, column, value)
- The list of triples is stored in a 1-D array

Single Linear List Example

0 0 3 0 4	list =
0 0 5 7 0	row
0 0 0 0 0	column
0 2 6 0 0	value

0	0	1	1	3	3
2	4	2	3	1	2
3	4	5	7	2	6

One Linear List Per Row

0 0 3 0 4	row0 = [(2, 3), (4,4)]
0 0 5 7 0	row1 = [(2,5), (3,7)]
0 0 0 0 0	row2 = []
0 2 6 0 0	row3 = [(1,2), (2,6)]

Approximate Memory Requirements

500 x 500 matrix with 1994 nonzero elements, 4 bytes per element

2-D array = $500 \times 500 \times 4 = 1 \text{ million}$ bytes

3-tuple Representation = $(3 \times 1994 \times 4) + 4 \times 4$
 = 23,944 bytes

Matrix Transpose

0 0 3 0 4	→	0 0 0 0
0 0 5 7 0		0 0 0 2
0 0 0 0 0		3 5 0 6
0 2 6 0 0		0 7 0 0
		4 0 0 0

Matrix Transpose

0 0 3 0 4	→	0 0 0 0
0 0 5 7 0		0 0 0 2
0 0 0 0 0		3 5 0 6
0 2 6 0 0		0 7 0 0
		4 0 0 0

row	0 0 1 1 3 3	→	1 2 2 2 3 4
column	2 4 2 3 1 2		3 0 1 3 1 0
value	3 4 5 7 2 6		2 3 5 6 7 4

Matrix Transpose

0 0 3 0 4	→	0 0 0 0
0 0 5 7 0		0 0 0 2
0 0 0 0 0		3 5 0 6
0 2 6 0 0		0 7 0 0
		4 0 0 0

row	0 0 1 1 3 3
column	2 4 2 3 1 2
value	3 4 5 7 2 6

Step 1: #nonzero in each row of transpose.

= #nonzero in each column of
original matrix

= [0, 1, 3, 1, 1]

Step2: Start of each row of transpose

= sum of size of preceding rows of
transpose

= [0, 0, 1, 4, 5]

Step 3: Move elements, left to right, from
original list to transpose list.

Matrix Transpose

Step 1: #nonzero in each row of transpose.

= #nonzero in each column of
original matrix

= [0, 1, 3, 1, 1]

Step2: Start of each row of transpose

= sum of size of preceding rows of
transpose

= [0, 0, 1, 4, 5]

Step 3: Move elements, left to right, from
original list to transpose list.

Complexity

$m \times n$ original matrix

t nonzero elements

Step 1: $O(n+t)$

Step 2: $O(n)$

Step 3: $O(t)$

Overall $O(n+t)$
